Reducing the Impact of Pharmaceutical Marketing to Physicians and Promoting Appropriate Prescribing and Drug Safety

The pharmaceutical industry spends nearly $30 billion annually on marketing. The majority (including samples) is spent on direct marketing to physicians (Donohue, NEJM, 2007).

Nationwide, prescription drug spending rose 500% (from $40.3 billion to 200.7 billion) between 2000 and 2005 (Kaiser Family Foundation, 2007).

This report was created in collaboration with

Cost-Effectiveness of Prescriber Education ("Academic Detailing") Programs

Individual prescriber education programs – often called "academic detailing" provide physicians with unbiased information, encouraging the use of the safest, most effective and – other things being equal – least costly drugs.

Such programs have been in use for more than 20 years, and have been consistently shown to change prescribing behavior. And individual educational outreach is demonstrably more effective than static practice guidelines or didactic presentations or group educational visits.

This paper reviews published studies and formal economic evaluations of academic detailing programs in a number of settings.

Arkansas, New Hampshire, Vermont, D.C. Medicaid Study

By one estimate, every dollar spent on an academic detailing program, returns two dollars in reduced drug costs. This number is from an economic model developed by researchers at Harvard Medical School and the Brigham and Women’s Hospital. It was based on a randomized controlled trial published in the New England Journal of Medicine, which compared the prescribing of doctors who were offered education visits with those who were not. These were doctors in the Medicaid programs of Arkansas, New Hampshire, Vermont or the District of Columbia, and the study showed that educational visits substantially and significantly reduced the number of...
prescriptions for three often over-used drugs.\(^1\)

That change in prescribing equated with a decrease in costs of about 20 thousand dollars for 141 doctors, more than enough to offset the cost of running the program.\(^2\) And those are savings were only for the first year of the program, and only to Medicaid, even though doctors also saw patients with other types of coverage. The real savings were almost certainly higher.

The researchers then modeled an expansion to a full-scale program involving ten thousand doctors a year, making projections for staffing and duration of effects. They concluded, as I’ve said, a most-likely benefit-to-cost ratio of 1.8 to 1.\(^3\)

It is important to note that the cost of prescription drugs has increased much more rapidly than the costs of labor since this early 1980s study. Medications that seemed expensive then would now be considered a bargain. That suggests even greater potential for present-day savings.

**Pennsylvania PACE Analysis**

The Pennsylvania Department of Aging, through its Pharmaceutical Assistance Contract for the Elderly (PACE) program provides academic detailing to physicians in a number of counties.\(^4\) The service is run by the Independent Drug Information Service, which is affiliated with Harvard Medical School. The program presents information on several classes of drugs, but a preliminary economic analysis focuses on just one class – the so-called “little purple pill” for acid-reflux and its cheaper, equally effective cousins.\(^vi\)

The analysis shows reduced drug costs of about $120 per doctor per month.\(^5\) Among the heaviest prescribers, the reduction was $378 per doctor per month. If these changes in prescribing persist for a year, they would equate to cost savings of $572 thousand, against total program costs of about $1 million.

---

\(^1\) \(n = 435\); intention-to-treat analysis; reduction in units prescribed after education visit: cephalaxin (\(p = 0.0006\)), propoxyphene (\(p = 0.04\)), papaverine (\(p = 0.02\)), all three drugs (\(p = 0.0001\)).

\(^2\) Savings of $105 per prescriber over the 9-mo study. Estimated year one savings = $19,740.

\(^3\) Cost per physician visit about $100.

\(^4\) Based on the projections that detailers would see average 5.4 physicians per day in the field and that behavior change effects decay to zero in year 2.

\(^5\) As of mid-2007, drug information consultants in this program had met with 716 physicians.

\(^6\) Comparing the seven months before and after the educational intervention, reductions were $122 per doctor per month compared with “control” doctors in the same county who did not receive educational visits (\(p = 0.05\)). Compared controls in other counties, the reduction was $124 (\(p = 0.09\)).
It is important to point out that these are savings only for a single class of drugs, and only for patients in the PACE program, who make up just a fraction of the caseload for any physician. In all likelihood, savings in other drug classes and savings to other programs, including Medicaid, Medicare Part D, state employees and private plans, would more than offset the cost of running the program.

**Australian Experience**

Academic detailing programs are extensively used in other countries, particularly in Australia and Canada.\(^vii\) While there are important differences between those healthcare systems and that of the United States, it is important to note that U.S. prescription drugs are generally considerably more costly. That may suggest the potential for even greater savings here.

In Australia, the National Prescribing Service program generated net savings of 300 million Australian dollars over ten years.\(^viii\) This is largest, longest running program in the world, involved 11,500 individual prescribers in 2006-2007 (a steady increase from 2,500 participants in 1998–99. Over a nearly ten-year period (1997-2005), estimated savings have consistently been greater than budgeted.

**Potential savings**

The potential to generate savings by improving prescribing is immense. By one estimate, increased use of generics\(^6\) would alone produce national savings of about $8.8 billion dollars per year.\(^ix\)

Looking only at a single condition, hypertension (high blood pressure), the evidence shows that for most patients the first choice drug should be an inexpensive thiazide diuretic instead of one of several new, expensive and heavily marketed drugs. The potential US saving from appropriate use of thiazides is estimated at $433 million a year.\(^x\) And published evidence shows that academic detailing drive this shift in a cost-effective way.\(^xi\)

**Non-drug Savings**

Beyond direct savings to the drug budget is an area of even greater potential cost savings – the potential to prevent disease. A change in prescribing that prevents a heart attack cuts costs across the entire healthcare system.

---

\(^6\) Based on data from a nationwide representative survey of the US population, generics account for 56% of all prescriptions – far lower than the 75-80% rate achieved in many of the best programs. The $8.8b is in year 2000 dollars.
One study of academic detailing showed enormous savings by preventing gastrointestinal bleeds.\textsuperscript{7} Another, in heart failure,\textsuperscript{xii} estimated a net cost of about twenty-five hundred dollars per year of life gained.\textsuperscript{8} That is a low price to pay to give someone an extra year of life.

**Other published studies**

Appendix A summarizes other published studies, which generally reflect the potential for savings. However, assessing the cost impact of educational outreach programs is challenging.\textsuperscript{xiv,xv} Experienced practitioners attest that the success of a program depends on the program focus and the training and skill level of the clinical educators. Longer running programs, where physicians and educators develop trusting relationships may be expected to increase the effectiveness of the intervention. However, most academic studies are short-term initiatives. Limited conclusions may be drawn from studies where failure to demonstrate a cost impact was secondary to failure to change behavior.

**Conclusion**

Much evidence supports the potential savings from appropriately applying information on the comparative effectiveness of drugs. But as the Congressional Budget Office recently noted,\textsuperscript{xvi} savings are realized only when the information is translated into changes in clinical practice. That is what academic detailing helps to achieve.
